

Search for new physics beyond the Standard Model in final states with jets and leptons+jets at CMS

Francesco Santanastasio^{1,a} on behalf of the CMS collaboration

¹ *Sapienza, University of Rome and INFN Rome*

Abstract. Searches for new physics beyond the Standard Model performed by the CMS experiment are presented in final states with jets and leptons+jets. The document focuses a selection of recent results from searches for heavy dijet resonances, leptoquarks, and heavy majorana neutrinos using proton-proton collision data at both $\sqrt{s}=8$ and 13 TeV. The novel CMS datascouting technique used to probe the low-mass region in hadronic final states is introduced and results from Run1 analysis are shown. A few interesting excesses of events in Run1 data observed in the leptons+jets channels are also discussed and the prospects for the future analyses using Run2 data are presented.

1 Introduction

Searches for new physics beyond the Standard Model performed by the CMS experiment at the CERN LHC are presented in these conference proceedings. A selection of searches in final states with jets and leptons+jets is shown¹. Results are obtained using proton-proton collision data collected in Run1 (2012) at $\sqrt{s} = 8$ TeV and Run2 (2015) at $\sqrt{s} = 13$ TeV. Section 2 presents results of the search for dijet resonances at high-mass using 2015 Run2 data and results of the low-mass analysis with the Run1 *data scouting* technique. Section 3 reports the results from searches for leptoquarks at $\sqrt{s} = 13$ TeV. In Section 4 a few interesting excesses of events in data observed in the Run1 searches for leptoquarks and heavy majorana neutrinos are discussed. Finally the future prospects for these searches are presented in Section 5.

2 Dijet resonances

The search for new resonances decaying to pairs of jets is among the most important ones at LHC because any hypothetical new particle that might be produced originates from the colliding protons and therefore it must couple to quarks and/or gluons.

The analysis strategy consists in reconstructing the invariant mass of the dijet system (m_{jj}) and searching for a resonant peak in its spectrum. Wide-jets (corresponding to a jet cone size of $\Delta R = \sqrt{\Delta\eta^2 + \Delta\phi^2} = 1.1$) are used to reconstruct the energy of the initial partons from the resonance decay. This algorithm improves the energy resolution by collecting final state radiation from

¹The complete list of publications and preliminary results on these subject are available in the CMS public web pages [1].

the outgoing partons. Events used for the search are required to have $\Delta\eta_{jj} = |\eta_{j1} - \eta_{j2}| < 1.3$ reducing significantly the QCD multijet background in t-channel with respect to the s-channel process of resonance production. The search is performed in two different dijet mass regions depending on the trigger strategy used: high-mass ($m_{jj} > 1$ TeV) and low-mass ($500 \text{ GeV} < m_{jj} < 1$ TeV).

2.1 High-mass dijet search

The high-mass analysis uses events collected by standard hadronic triggers employed in many CMS analyses. The trigger requires that events have $H_T > 800$ GeV, where H_T is the scalar sum of all jets with $p_T > 40$ GeV reconstructed at high level trigger (HLT). Offline events are required to pass a cut on the dijet mass at approximately $m_{jj} > 1$ TeV for which the trigger is fully efficient on events in data passing the final dijet selection.

Figure 1 (left) shows a display of the highest dijet-mass event passing the full selection, recorded by CMS during 2015 data taking. The reconstructed invariant mass of the dijet system is about 6 TeV. Figure 1 (right) shows the dijet mass spectrum in 2.4 fb^{-1} of data collected in 2015 at $\sqrt{s} = 13$ TeV [2]. The background is estimated by fitting the data with a smoothly falling function. The parametrization used is

$$\frac{d\sigma}{dm_{jj}} = \frac{P_0(1-x)^{P_1}}{x^{P_2+P_3 \ln(x)}} \quad (1)$$

where $x = m_{jj}/\sqrt{s}$. This function models well the QCD multijet simulation and the data and it has been successfully employed in previous searches at hadron colliders at different \sqrt{s} values. No sign of new resonances is observed in the dijet mass spectrum, and 95% confidence level (CL) upper limits are set on the resonance production cross section (σ) times branching ratio to dijet (BR) times acceptance (A) as a function of the hypothesized resonance mass. The limits are reported in Figure 2 (left) for different final states (quark-quark, quark-gluon, gluon-gluon depending on the resonance decay products). The upper limits on $\sigma \times BR \times A$ are compared to theoretical predictions for several new physics models including strongly coupled resonances (such as string resonances, excited quarks, axigluons, etc.) and weakly coupled resonances (such as Z' and W' bosons and Randall-Sundrum Gravitons), covering a wide range of cross sections to which this analysis is sensitive. Lower limits are set on the mass of these resonances as summarized in Figure 2 (right). The limits of this analysis significantly exceed the ones from the previous Run1 search thanks to the increased center-of-mass energy in Run2.

2.2 Low-mass dijet search with data scouting

It is important to extend the dijet search in the mass region below 1 TeV in order to probe hypothetical hadronic resonances with small couplings to quarks and gluons that similar searches performed at previous colliders could not find yet. The main experimental difficulties at LHC originate from the large cross section of multijet events at low dijet mass and the finite computing resources for processing and storing these data. To solve this issue, a new technique known as *data scouting* was first proposed by CMS in 2011 [3]. This technique, by significantly reducing the event size compared to the standard CMS data stream (about a factor 100), enabled CMS to relax the trigger thresholds and record fully hadronic events at a rate of few KHz to extend the search in the sub-TeV mass region. With this approach, the analysis is performed using jets reconstructed online in the CMS trigger computing farm.

This novel research strategy was fully integrated in the CMS physics program in 2012 [4] allowing to collect data corresponding to almost 19 fb^{-1} of integrated luminosity at $\sqrt{s} = 8$ TeV in the sub-TeV

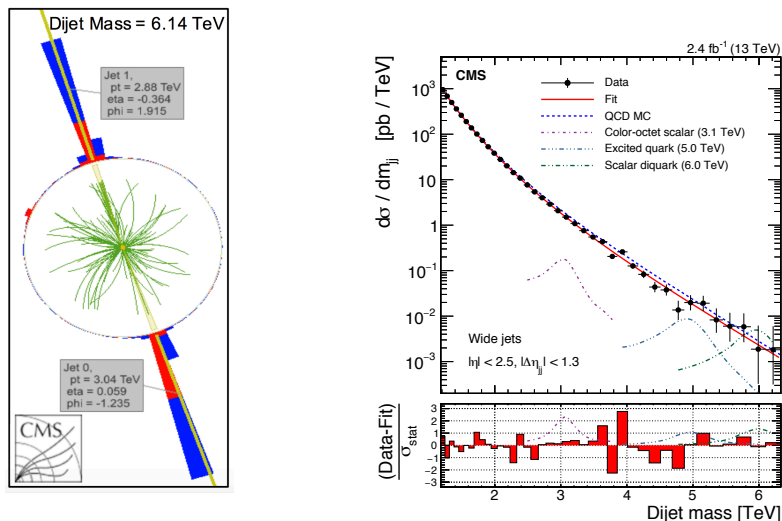

Figure 1. Left: Display of the event with the highest dijet mass (6.14 TeV) after the full selection. The transverse view with respect to the beam axis is shown. The kinematic quantities of the two wide jets are reported. Right: Dijet mass spectrum (points) compared to a fitted parameterization (solid curve) and to the prediction of the PYTHIA8 QCD MC event generator including simulation of the detector (dashed curve). The lower panel shows the difference between the data and the fitted parameterization, divided by the statistical uncertainties. The predicted distributions of narrow resonance signals for three models, with resonance mass values corresponding to the respective 95% confidence level exclusion limit, are shown in both panels (dash-dotted curves).

dijet mass region. The new trigger allows to go down to 400 GeV in dijet mass. The offline analysis strategy used for the high-mass analysis is also employed in this low-mass search. Figure 3 (left) shows the dijet mass spectrum in scouting data in the region between 400 and 1900 GeV. No sign of new resonances in observed and upper limits on $\sigma \times BR \times A$ are set as a function of the resonance mass. The analysis results has been published on the PRL journal in 2016 [5].

It is interesting to compare the limits of this search with those obtained by previous experiments at hadronic colliders with different center-of-mass energies. This can be done assuming a common theoretical model of a new resonance Z' that decays to a pair of quarks as described in Ref. [6]. This simplified model is characterized by only two free parameters: the resonance mass $M_{Z'}$ and the coupling g_B of the resonance to the quarks. The upper limits on signal cross section can be translated into limits in the coupling vs mass plane as shown in Figure 3 (right). The CMS dijet analysis with data scouting extends the search below 1 TeV and provides, at the time of the publication, the most stringent limits to date in the region between 500 and 800 GeV. In the region below 500 GeV the best limits still come from CDF and UA2 experiments. ATLAS and CMS have initiated recently a physics program targeting the mass region below 500 GeV using various techniques that exploit the emission of initial state radiation (quarks/gluons or photons) to trigger these events.

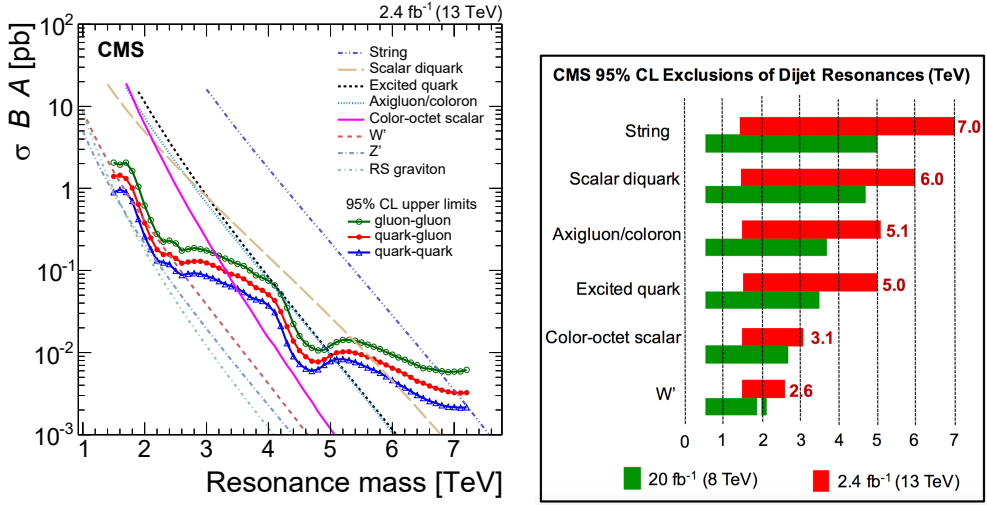

Figure 2. Left: The observed 95% CL upper limits on the product of the cross section, branching fraction, and acceptance for quark-quark, quark-gluon, gluon-gluon type dijet resonances. The limits are compared to the predicted cross sections of several resonance models. Right: Observed 95%CL lower limits on resonance mass for the listed models obtained by the CMS experiment in Run 1 (green) and Run 2 (red) analyses.

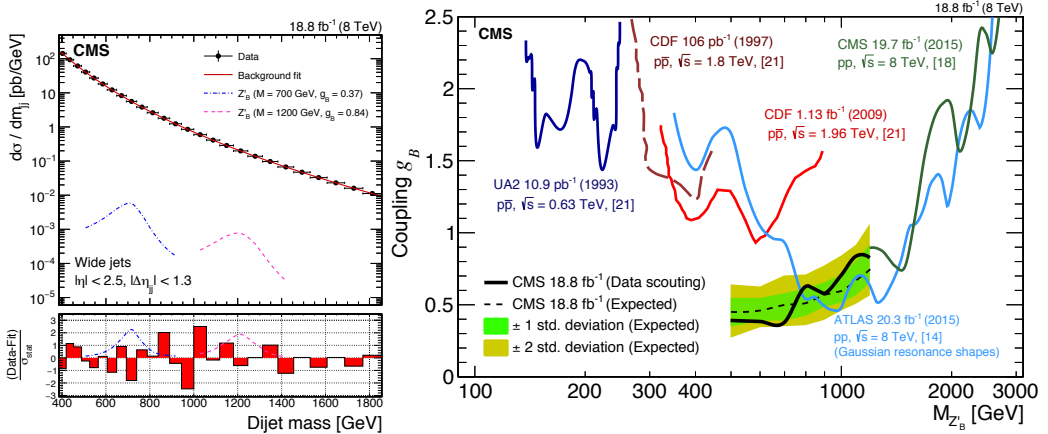

Figure 3. Left: Dijet mass spectrum using data scouting (points) compared to a fitted parameterization (solid curve). The bottom panel compares the data and the fit result, normalized by the statistical uncertainty in the data, for each bin. The predicted distributions of narrow resonance signals for a hypothetical leptophobic resonance Z' with two different mass and coupling values are shown in both panels (dash-dotted curves). This dijet mass distribution complements that observed in the high-mass analysis. Right: Observed 95% CL upper limits on the coupling g_B of the Z' resonance as a function of its mass. The results are compared to those obtained with similar searches at different collider energies.

3 Leptoquarks

The Standard Model contains hints that the lepton and quark sectors are related by a fundamental symmetry. Many beyond the Standard Model theories (such as grand unified theories, composite models, technicolor, SUSY RPV, and others) include such a symmetry, and predict the existence of new massive bosons called leptoquarks (LQ). Leptoquarks can have spin 0 or 1, are coloured particles, have fractional electric charge, and carry both baryon and lepton number. In order to avoid proton decay, baryon and lepton numbers must be conserved separately. In addition constraints from rare decays involving flavour-changing-neutral-currents suggests that LQs should only couple with leptons and quarks within the same generation.

In the simplest case, the model parameters are three: the mass of the LQ (M_{LQ}), the branching ratio of the LQ decay into charged lepton and quark (β), and the LQ-lepton-quark coupling (λ). The branching ratio of the LQ decay into neutrino and quark is $1 - \beta$. At LHC, LQs can be produced singly or in pairs. The pair production, which happens mainly via gluon-gluon fusion, is particularly interesting because it does not depend on the unknown coupling λ . The pair production cross section depends on the strong coupling and it is calculated at next-to-leading order.

Depending on the value of the parameter β different decay channels are possible from the pair production of LQs. They differ for the branching ratio (BR) and the observed final state, thus producing a wide range of experimental signatures:

- $\ell\ell jj$ channel, $BR = \beta^2$, two charged leptons plus two jets;
- $\ell\nu jj$ channel, $BR = 2\beta(1 - \beta)$, one charged leptons, missing transverse energy (MET) plus two jets;
- $\nu\nu jj$ channel, $BR = (1 - \beta)^2$, two jets plus MET.

Feynman diagrams for the different final states are shown in Figure 4.

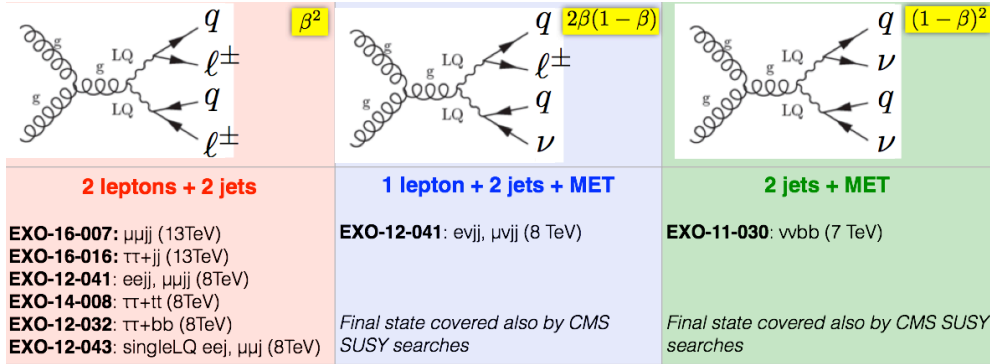

Figure 4. Feynman diagrams for different final states in LQ pair production processes. The labels EXO-XX-YYY indicates the identifier of the CMS publications or preliminary results describing the most recent searches in the corresponding channel [1].

The most recent searches for LQ at CMS have been performed using about 2 fb^{-1} of $\sqrt{s} = 13 \text{ TeV}$ data collected in 2015.

A search for second generation LQs is performed in final states with two muons and two jets [7]. The event selection, optimized for each LQ mass hypothesis, is based on three main kinematic observables: the di-muon invariant mass, the $S_T = p_T(\mu_1) + p_T(\mu_2) + p_T(jet_1) + p_T(jet_2)$ variable, and the lepton-jet mass $M_{\mu j}^{min}$ defined as the smaller of the two reconstructed LQ masses which minimizes

the LQ-LQ mass difference. In presence of a signal, the $M_{\mu j}^{\min}$ distribution would show a narrow peak in correspondence of the LQ mass, as shown in Figure 5 (left).

A search for third generation LQs is performed in final states with two taus (with reconstructed hadronic decays) and two jets [8]. The main physics observable to discriminate between signal and background is the variable $S_T = p_T(\tau_1) + p_T(\tau_2) + p_T(jet_1) + p_T(jet_2)$ shown in Figure 5 (right).

No excess of events is observed in data in these searches and lower limits are set on the mass of second and third generation LQs at 1150 GeV and 740 GeV, respectively, assuming $\beta = 1$.

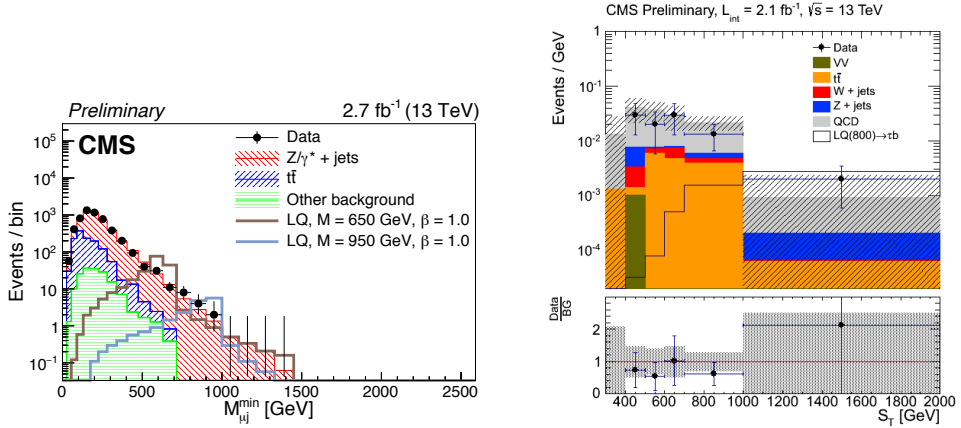

Figure 5. The $M_{\mu j}^{\min}$ distribution in events with two muons and two jets (left). The S_T distribution in events with two taus decaying hadronically and two jets (right). Distributions for the data, the background predictions, and the expected LQ signals are shown.

4 Excess of events in Run1 data

Searches for new physics in final states with leptons+jets have been performed also in Run1 data at $\sqrt{s} = 8$ TeV. Two of these searches in final states with electrons and jets are particularly interesting because they report an excess of events in data compared to the background prediction.

4.1 First generation leptoquarks

A search for first generation leptoquarks in the $evjj$ channel have been performed with about 20 fb $^{-1}$ of data [9]. The analysis is designed as a counting experiment in a signal region defined by an event selection optimized for each LQ mass hypothesis. The reconstructed observables used in the selection to separate signal from background are the electron-neutrino transverse mass, the variable $S_T = p_T(e_1) + MET + p_T(jet_1) + p_T(jet_2)$, and the electron-jet mass M_{ej} . Figure 6 (left) shows the electron-jet mass distribution after a selection optimized for the search of a LQ with 650 GeV mass. A broad excess of data events is visible above 600 GeV compared to the background expectation. This reflects also in the upper limits on signal cross section times branching ratio shown in Figure 6 (right) in the same LQ mass region. The local significance of the excess is 2.6 standard deviations. No excess is observed in the $\mu\nu jj$ channel.

Figure 6. Left: The M_{ej} distribution in the $evjj$ channel after the selection criteria optimized for a LQ mass of 650 GeV have been applied. Right: the expected and observed upper limits at 95% CL on the LQ pair production cross section times branching ratio as a function of the first generation LQ mass obtained in the $evjj$ channel.

4.2 W_R and heavy Majorana neutrinos

The second analysis is a search for W_R and heavy Majorana neutrinos [10]. These new heavy particles are predicted in left-right symmetric extensions of the Standard Model. The model introduces an additional right-handed $SU_R(2)$ symmetry group to the SM, which includes heavy charged (W_R^\pm) and neutral (Z_R) gauge bosons in addition to heavy right-handed Majorana neutrinos (N_e, N_μ, N_τ). The latter ones provide a possible explanation for the mass of SM neutrinos through the so called *see-saw* mechanism. Figure 7 (left) shows a diagram of the production and decay of a massive W_R gauge boson decaying to an heavy Majorana neutrino. The final state contains two charged, same-flavour leptons and two jets. In presence of a signal the invariant mass of the four-body system $M_{\ell\ell jj}$ peaks at the mass of the W_R boson. Figure 7 (right) shows the M_{eejj} distribution in data events with two electrons and two jets. An excess is visible at around 2 TeV corresponding to a local significance of 2.8 standard deviations. No excess is observed in the two muons plus two jets channel.

5 Future prospects

Searches in jets and leptons+jets final states at CMS are ongoing using the recent 2016 data. A datasample of about 40 fb^{-1} should be recorded at $\sqrt{s} = 13 \text{ TeV}$ for both ATLAS and CMS experiments. The sensitivity to new physics of the searches presented in this document will improve significantly compared to the current results thanks to a dataset 20 times larger than 2015.

At the date of this conference, the two searches discussed in Section 4 have not being repeated yet at $\sqrt{s} = 13 \text{ TeV}$ neither by ATLAS or CMS experiments. Although the observed excesses are still compatible with statistical fluctuations of the background, it is very interesting to see if the new analyses will confirm the results observed in the 8 TeV data. New results from the CMS collaboration are expected in 2017.
